AB Teicoplanin is a macrocyclic glycopeptide that is highly effective as a chiral selector for LC enantiomeric sepns. Two possible interaction paths were studied and related to solute retention and selectivity: (1) interactions with the only teicoplanin amine group and (2) role of hydrogen bonding interactions. Mobile phases contg. 0.5 and 5 mM copper ions were used to try to block the amine group. In the presence of copper ions, the teicoplanin stationary phase has a decreased ability to sep. most underivatized racemic amino acids. However, it maintained its ability to sep. enantiomers that were not .alpha.-amino acids. There is little copper-teicoplanin complex formation. The effect of Cu²⁺ on the enantiosepn. of some .alpha.-amino acids appears to be due to the fact that these solutes are good bidentate ligands and form complexes with copper ions in the mobile phase. Isotopic exchange with deuterium oxide was performed using acetonitrile-heavy water mobile phases. The retention times of all amino acids were lower with deuterated mobile phases. The retention times of polar or apolar mols. without amine groups were higher with deuterated mobile phases. In all cases, the enantioselectivity factors were unaffected by the deuterium exchange. Probably the electrostatic interactions are decreased in the deuterated mobile phases and the solute-accessible stationary-phase vol. is somewhat swollen by deuterium oxide. The balance of these effects is a decrease in the amino acid retention times and an increase in the apolar solute retention time. The enantioselectivity factors of all of the mols. remain unchanged because all of the interactions are changed equally. The authors propose a new global quality criterion (the E factor) for comparing and evaluating enantiomeric sepns.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB D,L-Amino acid enantiomers are sepd. by capillary zone electrophoresis (CZE) as 5-dimethylamino- 1-naphthalene sulfonyl (dansyl) derivs. using a Cu²⁺-L-aspartyl-L-phenylalanine Me ester (aspartame) **complex** as a chiral selector in the buffer. Only partial enantiomeric resolu. was obtained for several dansyl-D,L-amino acids and for the most favorable cases resolu. approaches .apprx.1.4. Increasing Mg²⁺, Cd²⁺, or Zn²⁺ concn. in a 10 mM NH₄OAc, 2.5 mM Cu²⁺, 5.0 mM aspartame, pH = 7.40 buffer increases dansyl-D,L-amino acid migration time, increases migration time difference between the D-enantiomer, which appears 1st in the electropherogram, and the L-enantiomer, and resolves the enantiomers of most dansyl-D,L-amino acids with resolu. values in the range of 1.4 to >5.0 depending on the deriv. and buffer conditions. An increase in the buffer divalent cation concn. reduces the electroosmotic flow (EOF) while the electrophoretic mobilities of the dansyl-D,L-amino acid enantiomers do not undergo significant change as the divalent cation concn. increases. The improved resolu. between the dansyl-D,L-amino acid enantiomers is due to the reduced EOF and small differences in the ternary **complex** formed between the dansyl-D,L-amino acid enantiomers and the Cu²⁺-aspartame **complex**.

AB Cu(II) complexes of L-amino acid amides added to the eluent in
reversed-phase HPLC are able to perform chiral discrimination of
unmodified amino acids with high enantioselectivity. The mechanism is
consistent with a ligand exchange between the binary initial Cu(II)
complex and the enantiomers. Evidence is provided that the
exchange of the ligand is actually occurring during the chromatog. sepn.
The system involves equil. of exchange in the aq. soln., in the stationary
phase and between the 2 phases. Enantioselectivity is essentially due to
the adsorption of the diastereomeric ternary species on the column,
whereas the relative stabilities of the mixed complexes in the mobile
phase seem to be negligible with respect to the overall discrimination
process. The structural features of the initial Cu complexes greatly
affect the stereoselectivity of the process. The chromatog. parameters
(pH, selector concn., eluent polarity, ionic strength) are examd.

AB The 6-O-carboxymethylated chitin(6-O-CM-chitin) has the highest affinity toward Ca ion among divalent metal ions. But Cd, Pb, Ni, and Ba ions adsorb on CM-chitin with remarkably higher affinity than Ca by additive carboxymethylation at the 3-O-hydroxyl group(3,6-O-CM-chitin). The absorption capacity of neutral amino acids on 6-O-CM-chitin is increased by Ca ion. The adsorption profile of neutral amino acids cannot be explained only by the side chain hydrophobicity phenylalanine is adsorbed on Ca-chelated CM-chitin with extremely high affinity. The specific affinity for the phenylalanine side chain is retained for the peptides contg. phenylalanine.

AB Among various divalent metal ions, Ca has been found to be adsorbed tightly onto carboxymethylchitin. The adsorption was completed not only by induced carboxyl groups but also by the support of acetamide, as well as primary and secondary hydroxyl groups. Although the adsorption capacity for transition metal ions was enhanced appreciably by regeneration into fibrous form, only that of Ca ion, among alkali-earth metals, was at the same level as that of transition metals. Since little effect was shown on the adsorption of phenylalanine by the blocking of .alpha.-amino and .alpha.-carboxyl groups of L-phenylalanine, and since D-phenylalanine was so little adsorbed, the chiral specific adsorption of phenylalanine might be supported by mediation of the Ca ion and by the contribution of hydrophobicity of the .beta.-Ph group.

AB A simple thin-layer chromatog. method for the sepn. of D- and L-dansylamino acids using a new resolving agent is described. The enantiomeric resoln. of racemates was accomplished on reversed-phase plates pretreated with a poly-L-phenylalaninamide-copper(II) complex using water-acetonitrile mixts. as eluent under isocratic conditions. The polymeric ligand was easily prepd. by reaction of the optically active amide with ethylene glycol diglycidyl ether at room temp. The method is rapid and sensitive, and was successfully employed to resolve various dansylamino acids.

TITLE: Optically selective adsorption of .alpha.-amino acids
on montmorillonite-Cu-1-lysine complexes in
high-pressure liquid chromatography

CORPORATE SOURCE: Inst. Soils Water, Agric. Res. Organ., Bet Dagan,
50-250, Israel

LANGUAGE: English

AB Optically active cationic complexes adsorbed on montmorillonite can be used for the resolu. of racemic mixts. Montmorillonite-Cu-lysine systems were used as a solid phase in HPLC for the resolu. of the optical isomers of .alpha.-amino acids. Selectivity consts. >1.5 were measured for phenylalanine and tryptophan. The selectivity consts. for the amino acids contg. satd.-hydrocarbon side chains were in the range of 1.25-1.44. The

montmorillonite-Cu-l-lysine **complex** displayed a stronger affinity for the l-isomers of .alpha.-amino acids than for the d-isomers at pH values near neutrality. Inasmuch as surface-catalyzed peptide formation on clays has been proposed as a step in chem. evolution, this stronger affinity between the clay-Cu-l-amino acid **complex** and l-amino acids might have been significant in prebiotic evolution. The mechanism of optical resoln. probably involved ligand exchange. Optimizing the choice of the optically active ligands and of the chelating cation in the chiral agent may improve the resoln. of the optical isomers.

AB The acidity consts. of the ligands S(-)- and R,S(.+.-)-malic, S(+)-citramalic, R,S(.+.-)-2-methylbutanedioic and 2,2-dimethylbutanedioic acid, the stability consts. of their binary complexes with Cu(II) and La(III) ions; the acidity consts. of R(+)-malic acid, R,S(.+.-)-citramlic; stability consts. of their binary Cu(II) complexes were detd. potentiometrically in 0.5 M aq. NaCl4 soln. at 25.degree. with the use of a glass electrode. The 1:1 complexes of citramalic acid with Cu(II) and La(III) were slightly more stable than the corresponding malic acid complexes. Potentiometric measurements confirmed the existence of stereoselectivity in the **complex** formation between Cu(II) and S(-)- and R,S(.+.-)-malic acid and S(+)- and R,S(.+.-)-citramlaic acid. The stereoselectivity was revealed as a difference between the **complex** species of the racemic and optically active forms. Racemic malic acid and citramalic acid form mononuclear and polynuclear complexes with Cu(II), but the optically active forms of malic and citramalic acid form only mononuclear complexes.

LANGUAGE: English

AB Highly selective sepn. of D- and L amino acids can be effected by reversed-phase chromatog. of mixed chelate complexes of the analyte acids with equimolar concns. of Cu(II) and an optically active second amino acid in the mobile phase. The stabilities of the formed diastereomeric ternary complexes will detd. the resoln. of enantiomers. By this approach, amino acids were resolved as the dansyl and O-phthalaldehyde (OPA) derivs. and imino acids were sepd. without derivatization. Resoln. of D and L dansyl amino acids was accomplished as the mixed complexes of Cu(II) with L-proline, L-arginine, L-histidine, and L-histidine Me ester as the second amino acids. Among the chiral ligands studied, L-histidine Me ester is unique in that it possesses both achiral selectivity for the dansyl amino acids and chiral selectivity for the resp. D and L enantiomers. With a mobile phase gradient of acetonitrile in a buffer contg. Cu(II) L-histidine Me ester complex, a stereoselective procedure for the anal. of D and L amino acid enantiomers was devised and it achieved the sepn. that the current amino acid analyzer failed. The mixed chelate metal complexation approach was extended to resolve OPA derivs. The free amino acid reacted with OPA in the presence of a chiral sulfhydryl reagent, N-acetyl-L-cysteine. HPLC of the derivs. was then performed on a reversed-phase column, with a mobile phase contg. Cu(II) L-proline, using fluorescence detection and resolved the optical isomers of the common primary amino acids. The same approach was also used to resolve compds. contg. amine and sulfhydryl groups. The simultaneous detection and resoln. of D and L imino acids is a more complicated problem. The reason is that the nitrogen of the imino acids must be derivatized in order to be detected, whereas both the carboxyl and the imino groups must be free to allow complexation for chiral sepn. A procedure for the resoln. of D and L isomers of pipecolic acid and proline was devised by complexing the analytes with Cu(II)-L-aspartame and detecting the complexes at UV 235 nm. The urine concn. of D and L pipecolic acid was also measured this way for patients with disorders of lysine metab.

AB Highly selective sepn. of amino acids was accomplished by reversed-phase chromatog. of mixed chelate complexes of the acids with equimolar concns. of Cu(II) and an optically active 2nd amino acid in the mobile phase. Resoln. of D- and L-dansyl-amino acids was accomplished this way by using L-proline or L-histidine as the 2nd amino acids. The mixed chelation approach was extended to resolve o-phthalaldehyde (OPA) derivs. The free amino acid was reacted with OPA in the presence of N-acetyl-L-cysteine. HPLC of the deriv. was then performed on a reversed-phase column, with a mobile phase contg. L-proline and Cu(II), by using fluorescence detection. All primary amino acids reacted rapidly with OPA without measurable side products. The optical isomers were resolved. Study of the mechanism of optical selectivity confirmed that the chiral sulfhydryl reagent was responsible for the formation of diastereomeric mixed chelate complex and for the resoln. of the isomers. The same approach was applied to resolve stereoisomers of amines and sulfhydryl compds.

AB Micro high-performance liq. chromatog. sepn. of dansyl-D,L-amino acids was examd. by using Cu(II)-L-histidine or Cu(II)-L-histidine Me ester as eluent. Parameters that affect the retention and the resolu. of dansyl-D,L-amino acids were examd. Gradient elution was used to sep. many pairs of amino acids in a single chromatog. run.

AB Resoln. of underivatized amino acid enantiomers by reversed-phase liq. chromatog. is described using chiral eluents contg. the copper(II) complexes of N-(p-toluenesulfonyl)-L-phenylalanine and N-(p-toluenesulfonyl)-D-phenylglycine. Resoln. of the enantiomers of neutral, basic, and acidic amino acids and their amides was accomplished on a octadecylsilyl bonded silica gel column. A chromatog. model is proposed that is based on dynamic ligand-exchange mechanism of DL-amino acid with tosylated amino acid-copper(II) complex on the chem. bonded phase.

AB The resolu. of the optical isomers of Dns-amino acids (Dns = dansyl) by high-performance liq. chromatog. with mixed chelate complexation is described. Addn. of Cu(II) complexes of L-histidine to the mobile phase resulted in resolu. of many D- and L-Dns-amino acids, including those with aliph., polar, and arom. substituents. With polar substituents, highly selective incorporation of the L-enantiomer into the ternary complex with increased retention on the column was obsd. The reverse occurred with amino acids with aliph. side chains; the D-isomers were incorporated preferentially. With arom. substituted amino acids, the resolu. was pH dependent. Substitution of Cu(II) complexes of L-histidine Me ester in the mobile phase dramatically reduced the stereoselectivity, although the isomers were still resolved. Cu(II) complexes of N-acetyl-L-histidine used in the mobile phase gave no stereoselectivity. Excellent sepns. of isomers were achieved with several of these systems. Many pairs of amino acids could be sepd. in the same chromatog. anal.

AB Underivatized amino acid enantiomers are sepd. by liq. chromatog. on reversed-phase (C-18) columns using a chiral mobile phase consisting of a Cu complex with L-proline. Post-column reaction with o-phthalaldehyde enables detection of picomole amts. of amino acids. Changing chirality of the mobile phase to D-proline reverses the elution order of the enantiomers indicating the formation during chromatog. of a diastereomeric complex of the enantiomer with the copper-proline complex.
